## 1 Motivation

This interface document is intended for the use of CSDL to aid in our understanding of the relationship between the hyperbase server (HBS) and the client program. It is to act as the base for discussing improvements to the hyperbase server. This document is broken up into several sections. The first gives an overview of HBS. Then we discuss how to connect to HBS followed by information about operations available in versions 2.0 and 2.1 respectively. The event mechanism is explained. Then we present on all possible function return values, node field values and operations and end with some proposed changes.

## 2 Overview of the Hyperbase Server

Hyperbase is a multiuser, database manager for HyperText applications. Hyperbase manages the nodes and links of the HyperText artifacts and provides a small set of generic operations. The HyperText clients use these operations for their own HyperText applications. The server is currently the bottleneck at the server.

We have expanded on the original set of operations. We have added an Append operation to append new nodes, a List operation to show all users currently connected to the server, a Shutdown operation to gracefully bring down the server, a Name operation, and a Message passing facility. We have also added a Disconnect operation now when a client disconnects only. The DISCONNECT now contains the c

### 3 Connecting to HBS

The HBS connects to newclients through a pipe, a ‘unique socket’ whose default value is 10008. The request to connect is made by calling the Unix systemcall connect().

The HBS sends three, four-byte integers through the unique socket. These numbers are necessary to establish more pipes for specific types of communication. Herein, these pipes will be referred to as the server’s write, read and event sockets. After each four-byte integer the server waits for the client to connect on that pipe. The first four-byte integer is the server’s write socket. Information to be sent to the client will be sent through this socket. The second four-byte integer is the server’s read socket. All requests and information must be sent to the server through this socket. The third four-byte integer is the event socket. Events will be sent to the client on this socket. Once these three sockets are established, the client sends the user’s name and then the name itself. The user’s name must be sent through the write socket and the user’s name must end with a null character. The user’s name of the message to be sent with the event socket must be terminated with a null character. Next it reads that many characters

Figure 1: Packet

Figure 2: Packet Expe

---

<sup>1</sup>Note the only time a string must be terminated with a null character is when sending a name. All user names in HBS are ‘null’ terminated.

## 4 Available Operations: ver 3.0

### 4.1 Read

This operation reads the specified key value of a given entity number. If successful, it returns the key value through its write socket.

The HBS reads the operation READ (the four-byte integer 1) from its read socket. Next it reads the entity number (a four-byte integer) from its read socket. Next it reads the key number (a four-byte integer). Next it reads the length of the data to be sent with the event (a four-byte integer). Next it reads that many characters from the read socket. The READ operation then sends out the return value (a four-byte integer) on the HBS's write socket. Then if the return value is 351 (Locked by other), it sends the length of the data (a four-byte integer) on its write socket. Next it sends that many characters to its write socket.

Figure 3: Packet Expected

Figure 4: Packet Sent Out by Re

## 4.2 Write

This operation writes information to a specific key of a given entity number.

The HBS reads the operation **WRITE** (the four-byte integer 2) from its read socket. Next it reads the entity number (a four-byte integer) from its read socket. Next it reads the key number (a four-byte integer). Next it reads from the read socket the length of the data to be written in the node (a four-byte integer). Next it reads that many characters from the read socket. Next it reads the length of the message with the event (a four-byte integer). Next it reads that many characters from the read socket. The **WRITE** operation then sends out the return value (a four-byte integer) on the HBS's write socket.

Figure 5: ~~Packet~~ **Packet Expected by Write**

Figure 6: ~~Packet~~ **Packet Returned by Write**

### 4.3 Create Node

This operation creates a new node. If successful, it returns the ID number of the newly created node. These node IDs are always even numbered and are reused after deletion.

The HBS reads the operation CREATE NODE (the four-byte integer 5) from its read socket. Next it reads the length of the message to be sent with the event (a four-byte integer). Next it reads that many characters from the read socket. The

CREATE NODE operation then sends out the return value (a four-byte integer) on the HBS's write socket. If the return value is equal to 0 it sends the new entity number (a four-byte integer) to its write socket.

Figure 7: Packet Expected by Create Node

Figure 8: Packet Sent Out by Create Node

#### 4.4 Delete

This operation deletes the given entity (node or link). Deletion will fail for nodes if it is linked with another node. Deletion will fail for links if its 'From' entity still points to it. This operation ignores the fact that a node or link may be subscribed to the event mechanism or that a client may own a lock on it.

The HBS reads the operation DELETE (the four-byte integer 6) from the read socket. Next it reads the entity number (a four-byte integer) from the read socket.

Next it reads the length of the message to be sent with the event mechanism from the read socket.

Next it reads that many characters from the read socket. Then it sends out the return value (a four-byte integer) on the write socket.

Figure 9: Packet Expected by Delete

Figure 10: Packet Returned by Delete

## 4.5 Link

This operation is a remnant from the original hyperbase. A more complete version will be available in HBS 2.1.x. This operation will do one of two things. First, if the 'To' entity number is a node, then a link will be created and the ID number of the newly created link will be returned. Note that this link points to the given node, but the node points to this link yet. To establish this connection, one would need to do the LINK operation again in the following context. If the 'From' entity number is a node and the 'To' entity number is a link, then this operation establishes a connection between the two. That is, the node has as one of its outgoing links the link ID. The HBS reads the operation LINK (the four-byte integer). Next it reads the 'From' entity number (a four-byte integer). Then it reads the 'To' entity number (a four-byte integer). It then reads the length of the message to be sent with the LINK operation. If that many characters from the read message are available, the return value (a four-byte integer) is equal to 0 it sends the message. If not, then a new Link is created and its ID is returned.

Figure 12: Packet Structure

## 4.6 Move Link

This operation changes the destination node for an existing link.

The HBS reads the operation **MOVE LINK** (the four-byte integer 8) from its read socket. Next it reads the **Link** number (a four-byte integer) from its read socket. Next it reads the 'To' **Node** number (a four-byte integer) from its read socket. Next it reads the length of the message to be sent with the event (a four-byte integer). Next it reads that many characters from the read socket. The **MOVE LINK** operation then sends out the return value (a four-byte integer) on the HBS's write socket.

Figure 13: **Packet Expected by MoveLink**

Figure 14: **Packet Returned by MoveLink**

## 4.7 Remove Link

This operation destroys the conceptual connection between a given node and one of its outgoing links. Note that no nodes or links are deleted. Use Delete for deleting nodes and links.

The HBS reads the operation REMOVE LINK (the four-byte integer 9) from its read socket. Next it reads the **Node** number (a four-byte integer) from its read socket.

Next it reads the **Link** number (a four-byte integer) from its read socket. Next it reads the length of the message to be sent with the event (a four-byte integer). Next it

reads that many characters from the read socket. The REMOVE LINK operation then sends out the return value (a four-byte integer) on the HBS's write socket.

Figure 15: Packet Expected by RemoveLink

Figure 16: Packet Returned by RemoveLink

## 4.8 Event

This operation allows the client to subscribe to a particular event involving an entity and the operation on that entity at a given key. Each combination of an event must be subscribed to separately. However, it is possible to subscribe to mass entities, operations or keys using the 'ALL' code represented by the number 0.

The HBS reads the operation EVENT (the four-byte integer 10) from its socket. Next it reads the entity number (a four-byte integer) from its read socket. Next it reads the operation number (a four-byte integer). Next it reads the length of the message to be sent with the operation (a four-byte integer). Next it reads that many characters from the read socket. Next it reads the return value (a four-byte integer) from the read socket.

Figure 17: **Packet Expected by Event**

Figure 18: **Packet Returned by Event**

## 4.9 UnEvent

This operation allows the client to unsubscribe himself from a particular event involving an entity and the operation on that entity at a given key. The one restriction here is that once a client subscribes to all nodes for any combination of operation or key, can only unsubscribe himself from all nodes. Unsubscribing in this fashion cause an error. It will simply be ignored.

The HBS reads the operation UNEVENT (the four-byte integer 11) from its socket. Next it reads the entity number (a four-byte integer) from its socket. Next it reads the operation number (a four-byte integer). Next it reads the length of the message to be sent (a four-byte integer). Next it reads that many characters from the socket. Next it reads the return value (a four-byte integer) from the socket.

Figure 19: Packet Expected by UnEvent

Figure 20: Packet Returned by UnEvent

#### 4.10 Show Event

This operation displays a list of clients subscribing to a particular event involving an entity and the operation on that entity at a given key.

The HBS reads the operation `SHOWEVENT` (the four-byte integer 12) from its read socket. Next it reads the entity number (a four-byte integer) from its read socket.

Next it reads the operation number (a four-byte integer). Next it reads the key number (an integer). Next it reads the length of the message to be sent with the four-byte integer). Next it reads that many characters from the read

`SHOWEVENT` operation then sends out the return value (an integer) on

write socket. Then if the return value is equal to 0 it sends the length

containing a list of users subscribed to the event (a four-byte

that many characters to the write socket. Note that the

more names delimited by a newline character.

Figure 21: Packet Expected by ShowEvent

Figure 22: Packet Sent Out by ShowEvent

#### 4.11 Lock

This operation allows the client to lock any writable key at the given entity. Once a client obtains a lock, no other client may perform the write operation on the locked key.

The HBS reads the operation LOCK (the four-byte integer 13) from its read socket. Next it reads the entity number (a four-byte integer) from its read socket. Next it reads the key number (a four-byte integer). Next it reads the length of the message sent with the event (a four-byte integer). Next it reads that many characters from the read socket. The LOCK operation then sends out the return value (a four-byte integer) on the HBS's write socket.

Figure 23: Packet Expected by Lock

Figure 24: Packet Returned by Lock

#### 4.12 UnLock

This operation allows the client to unlock a particular key at the given entity.

The HBS reads the operation UNLOCK (the four-byte integer 14) from its read socket. Next it reads the entity number (a four-byte integer) from its read socket. Next it reads the key number (a four-byte integer). Next it reads the length of the message to be sent with the event (a four-byte integer). Next it reads that many characters from the read socket. The UNLOCK operation then sends out the return value (a four-byte integer) on the HBS's write socket.

Figure 25: Packet Expected by UnLock

Figure 26: Packet Returned by UnLock

### 4.13 Show Lock

This operation displays the client that currently holds a lock on a particular key at a given entity.

The HBS reads the operation SHOWLOCK (the four-byte integer 15) from its read socket. Next it reads the entity number (a four-byte integer) from its read socket. Next it reads the key number (a four-byte integer). Next it reads the length of the message to be sent with the event (a four-byte integer). Next it reads that many characters from the read socket. The SHOWLOCK operation then sends out the return value (a four-byte integer) on the HBS's write socket. Then it sends the length of the name or an error message (a four-byte integer) to the write socket. Next it sends that many characters to the write socket.

Figure 27: Packet Expected by ShowLock

Figure 28: Packet Sent Out by ShowLock

#### 4.14 Disconnect

This operation disconnects the client from the server process. In doing so, the client is automatically unsubscribed from all events and all the client's locks are released.

The HBS reads the operation DISCONNECT (the four-byte integer 17) from its read socket. Next it reads the length of the message to be sent with the event (a four-byte integer). Next it reads that many characters from the read socket. The DISCONNECT operation then sends out the return value (a four-byte integer) to the HBS's write socket.

Figure 29: Packet Expected by Disconnect

Figure 30: Packet Returned by Disconnect

#### 4.15 Browse

This operation allows the client to obtain a list of all node or link IDs currently in the database. The client specifies the node type (data or link) and a list of nodes or links is returned respectively.

The HBS reads the operation **BROWSE** (the four-byte integer 18) from its read socket. Next it reads the type of entity (a four-byte integer, 0 for **Node**, 1 for **Link**). Next it reads the length of the message to be sent with the event (a four-byte integer). Next it reads that many characters from the read socket. The **BROWSE** then sends out the return value (a four-byte integer) on the HBS's write socket. If the return value is equal to 0 it sends the length of the string (a four-byte integer). Next it sends that many four-byte integers from the write socket.

Figure 31: Packet Expected by

Figure 32: Packet Sent Out by Browse

#### 4.16 Shut Down Server

This operation allows a client to shut down the server. However, the server will only shut down if the requesting client is the last client connected to the server or send an error code if unsuccessful.

The HBS reads the operation SHUTDOWN (the four-byte integer 19) from its read socket. The SHUTDOWN operation then sends out the return value on the HBS's write socket.

- This operation is a new addition of version 2.0

Figure 33: ~~Packet Expected by Shut Down~~

Figure 34: ~~Packet Returned by Shut Down~~

#### 4.17 Show Users

This operation returns the number of clients currently connected followed by a list of names of those clients.

The HBS reads the operation SHOWUSERS (the four-byte integer 20) from its read socket. Next it reads the length of the message to be sent with the event (a four-byte integer). Next it reads that many characters from the read socket. The SHOWUSERS operation then sends out the return value (a four-byte integer) on the HBS's write socket. Next HBS sends the user count (a four-byte integer) to its write socket.

For each user, it sends the length of the user name (a four-byte integer) and the user name (a four-byte integer) to its write socket.

- This operation is a new addition of version 2.0

Figure 35: Packet Expected by ShowUsers

Figure 36: Packet Sent Out by ShowUsers

#### 4.18 Append

This operation appends text to the data field in a given entity.

The HBS reads the operation APPEND (the four-byte integer 21) from its read socket. Next it reads the entity number (a four-byte integer) from its read socket.

Next it reads from the read socket the length of the data to be appended to the node (a four-byte integer). Next it reads that many characters from the read socket. Next it reads the length of the message to be sent with the event (a four-byte integer).

Next it reads that many characters from the read socket. The APPEND operation then outputs the return value (a four-byte integer) on the HBS's write socket.

- This operation is a new addition of version 2.0

Figure 37: Packet Expected by Append

Figure 38: Packet Returned by Append

#### 4.19 Create Node with Name

This operation creates a new node and writes a given name to the name field. If successful, it returns the even-numbered ID of the newly created node.

The HBS reads the operation CREATE\_NODE\_WNAME (the four-byte integer 24) from its read socket. Next it reads the length of the name (a four-byte integer) to be written to the name field. Then it reads in that many characters from the read socket. Next it reads the length of the message to be sent with the event (a four-byte integer). Next it reads that many characters from the read socket. The CREATE\_NODE\_WNAME operation then sends out the return value (a four-byte integer) on the HBS's write socket. If the return value is equal to 0 it sends the new entity number (a four-byte integer) to its write socket.

Figure 39: Packet Expected by CreateNodeWithName

Figure 40: Packet Returned by CreateNodeWithName

#### 4.20 Create Link with Name

This operation creates a new link, writes a given name to its name field and establishes a connection with its 'From' node and its 'To' node. If successful, it returns the odd-numbered ID of the newly created link.

The HBS reads the operation CREATELINK.WNAME (the four-byte integer 25) from its read socket. Next it reads the 'From' entity number (a four-byte integer) from its read socket. Next it reads the 'To' entity number (a four-byte integer) from its read socket. Next it reads the length of the name (a four-byte integer) to be written to the name field. Next it reads that many characters from the read socket. Next it reads the length of the message to be sent with the event (a four-byte integer). Next it reads that many characters from the read socket. The CREATELINK.WNAME operation then sends out the return value (a four-byte integer) on the read socket. Then if the return value is equal to 0 it sends the entity number of the newly created link.

Figure 41: Packet Expected by Create Link with Name

Figure 42: Packet Returned by Create Link with Name

#### 4.21 Message

This operation allows a client to send a message to all clients that have subscribed to the events for the particular node and key.

The HBS reads the operation MESSAGE (the four-byte integer 26) from its read socket. Next it reads the entity number (a four-byte integer), the key (a four-byte integer), the length of the message (a four-byte integer) and finally the message (the message) from the read socket. The HBS creates a

sends it to all clients that have subscribed to events for the given node and key. The HBS returns `OK` through the write socket.

#### 4.22 Connected

This operation tells the HBS to listen to other clients and end the special connect mode.

The HBS reads the operation `CONNECTED` (the four-byte integer 27) from the read socket. It then reads in the length of the message (a four-byte integer) and that many bytes (the message) from the read socket. The HBS returns `OK` on the write socket.

#### 4.23 Create Node with Name and Data

This operation creates a new node, writes a given name to the name field and writes the given data to the data field. If successful, it returns the even-numbered ID of the newly created node.

The HBS reads the operation `CREATE_NAME_DATA` (the four-byte integer 28) from its read socket. Next it reads the length of the name (a four-byte integer) written to the name field. Then it reads in that many characters from the read

socket. Next it reads the length of the data to be placed in the node (a four-byte

integer). Next it reads that many characters from the read socket. Next it reads

the message to be sent with the event (a four-byte integer). Next it reads

that many characters from the read socket. The `CREATE_NAME_DATA` operation

sends out the return value (a four-byte integer) on the HBS's write socket.

If the return value is equal to 0 it sends the new entity number (a four-byte integer)

#### 4.24 Create Node with Name, Data and Lock

This operation creates a new node, writes a given name to the name field, writes the given data to the data field and acquires the lock on the data field.

If successful, it returns the even-numbered ID of the newly created node.

The HBS reads the operation `CREATE_NAME_DATA_LOCK` (the four-byte integer 29) from its read socket. Next it reads the length of the name (a four-byte

integer) to be written to the name field. Then it reads in that many characters from the

read socket. Next it reads the length of the data to be placed in the node (a four-byte

integer). Next it reads that many characters from the read socket. Next it reads

the message to be sent with the event (a four-byte integer). Next it reads

that many characters from the read socket. The `CREATE_NAME_DATA_LOCK` operation

sends out the return value (a four-byte integer) on the HBS's write socket.

If the return value is equal to 0 it sends the new entity number (a four-byte integer)

and the lock on the data field.

#### 4.25 Delete Link

This operation deletes a link and removes the reference to that link from the data node that points to the link.

The HBS reads in the operation `DELETELINK` (the four-byte integer 31) from the read socket. It then reads in the source node number (a four-byte integer), the link node number (a four-byte integer), the length of the message (a four-byte integer) then message length bytes (the message) from the read socket. The HBS sends out a return value (a four-byte integer) out the write socket.

#### 4.26 Create a Link to a New Node

This operation creates a new node and then creates a new link to that new node from the supplied source node.

The HBS reads in the operation `LINKNEWNODE` (the four-byte integer 32) from the read socket. It then reads in the source node number (a four-byte integer), the length of the new node's name (a four-byte integer), that many bytes (the new node's name), the length of the new link's name (a four-byte integer), that many bytes (the new link's name), the length of the message (a four-byte integer) then message length bytes (the message) all from the read socket. The HBS sends out a return value (a four-byte integer) out the write socket. If the return value is successful then the HBS sends out the new link's node ID (a four-byte integer) to the write socket.

#### 4.27 Write and Unlock the Node

This operation writes out to disk the field of the node and then unlocks that field of the node.

The HBS reads the operation `WRITE` (the four-byte integer 33) from the read socket. Next it reads the entity number (a four-byte integer). Next it reads the key number (a four-byte integer), the length of the data to be written (a four-byte integer), that many characters from the read socket, that many characters from the read socket, and finally the length of the message (a four-byte integer) on the read socket.

## 5 Events

Once a client subscribes to Events, by using the EVENT operation, the HBS will automatically send the client events. The HBS screens all activity in the Hyperbase and sends the client all events that the client has subscribed to. The HBS sends the events to the event socket for that client. The client then just has to read from the socket to get the event. If the HBS sends more than one event to the client, the events are just in a queue in the socket. The format of each event is as follows:

- name (a 'null' terminated string),
- entity number (a four-byte integer),
- operation number (a four-byte integer),
- operation occurred (a four-byte integer),
- length of a message (a four-byte integer),
- the message from the user who performed the operation.

Figure 43: Event Packet sent out
